SPECIFICATIONDIFFUSION PLATE HAVING DIFFERENT SECTIONS WITH  
DIFFERENT REFRACTIVE INDICES AND LIQUID CRYSTAL  
DISPLAY USING THE SAMEBACKGROUND OF THE INVENTION1. Field of the Invention

[0001] The present invention relates to a diffusion plate having diffusion sections with different refractive indices, and a liquid crystal display (LCD) using the diffusion plate.

2. Description of Prior Art

[0002] A liquid crystal display is capable of displaying a clear and sharp image over a wide area. It is thus used with various devices in which messages and/or pictures need to be displayed. However, a liquid crystal itself does not emit light, therefore, it has to be backlit by a light source to display the messages and/or pictures.

[0003] In an ideal liquid crystal display, the backlight element provides light evenly distributed across the entire surface of the display area. In addition, the apparatus has to meet the requirements of being small in size, light in weight, and sufficiently bright with low power consumption.

[0004] US Pat No. 5,438,484 issued to Kanda et al. discloses a surface lighting device. A variety of prior art surface lighting devices are disclosed in Figures 1 to 5 of the Kanda patent. The light source arranged in the surface lighting device shown is generally referred to as an "edge-type light source." Kanda describes the disadvantages of the prior art surface lighting device in detail, i.e., the surface areas closer to the light sources are brighter than the central area. According to Kanda's explanation in the specification, "However, as described above, the surface light device of an edge type has a low luminance in the central portion between the light sources and a high luminance in the vicinity of the light sources as indicated by a broken line C shown in FIG. 9. This is because the light sources 1a and 1b emit diffusion light and make the

vicinity of the light sources 1a and 1b bright while the light emitted from the light sources 1a and 1b mostly reach the opposite light source 1b and 1a to be diffused, respectively, thus making the vicinity of the light sources 1a and 1b brighter. As a result, it is inevitable that the effective light range (effective emission surface) of the foregoing lighting device will become narrower because its overall luminance must be adjusted to match evenly as a backlight with the lowered luminance between the central portion between the light sources 1a and 1b. Thus, a problem is encountered that the light utilization efficiency for the apparatus as a whole is reduced." See Column 2, lines 31 to 49.

[0005] Kanda provides a solution, such as shown in Figures 11 to 16, by providing "a light guide configured by a plural light transmitting members joined together, so that the junction surface therebetween crosses the light emitting surface." As a result and according to Kanda, the luminance emitted from edge-type light sources is evenly distributed across the entire area.

[0006] Kanda provides another solution in Figures 17 to 23, typically shown in Figure 23. In this application, the light source is arranged directly behind the liquid crystal display, instead of at the edge of a light guide, as shown in Figure 1 of the Kanda patent. However, this arrangement indeed provides a brighter central displaying area, but creates a problem of color chromaticity across the liquid crystal display. This is explained by Kanda in Column 12, lines 19-49 thereof. Kanda then uses a "light source having preferably be more blueish than the standard color" to solve the "yellowish" problem.

[0007] Aside from use of the "blueish light source," it is noted that a "light curtain," reference numeral 14 of Figure 22, has also been used to reduce the luminance projected toward the display area immediately in front of the light source. It should be easy to appreciate that the more parts used within the liquid crystal display, the more laborious the effort needed to assemble the display. No doubt, the size and weight of the liquid crystal display will inevitably be increased.

[0008] US Pat No. 5,881,201 issued to Khanarian discloses improved lightpipes for backlighting liquid crystal display devices. The lightpipes comprise transparent polymers with scattering centers. A preferred

composition for such lightpipes comprises a cycloolefin polymer containing scattering centers from suitable elastomers and inorganic fillers. The inventive lightpipes offer superior scattering efficiency as well as spatial uniformity of scattering and uniformity of scattering across a wide wavelength range.

[0009] According to Khanarian, the scattering centers are evenly distributed within the entire lightpipe so as to increase the luminance thereof.

### SUMMARY OF THE INVENTION

[0010] It is an object of the present invention to provide a diffusion plate such that the central area thereof is intensively brighter by creating a diffusion area having a different refractive index compared to the remaining area of the diffusion plate.

[0011] A preferred embodiment of the present invention provides a liquid crystal display comprising: a diffusion board having an emitting surface and an incident surface opposite to the emitting surface; and a light source arranged behind the incident surface. The diffusion board forms an ordinary diffusion section and an intensified diffusion section. The intensified diffusion section has a refractive index higher than that of the ordinary diffusion section, and corresponds to the light source in shape and position, thereby eliminating a "shadow" image of the light source when viewed from the liquid crystal display.

### BRIEF DESCRIPTION OF THE DRAWINGS

[0012] Figure 1 is a perspective view of a liquid crystal display made in accordance with the present invention.

[0013] Figure 2 is a cross sectional view of a diffusion board made in accordance with the present invention.

[0014] Figure 3 is a top plan view of a light source in accordance with the present invention.

### DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS OF THE INVENTION

**[0015]** Referring to Figures 1 and 2, a liquid crystal display made in accordance with the present invention generally includes a refractor frame 210 in which a plurality of light sources 220 are arranged. The refractor frame 210 further includes a diffusion board 230, and an enhancer 240.

**[0016]** The diffusion board 230 defines an incident surface 231 and an emitting surface 232. The light sources 220 are arranged adjacent to the incident surface 231, while the enhancer 240 is arranged adjacent to the emitting surface 232. The refractor frame 210 is further coated with a reflective film 211 so as to increase the luminance of the light sources 220 by reflecting the light beams emitted therefrom.

**[0017]** As mentioned in the prior art, when the light sources 220 are arranged directly beneath the diffusion board 230, it is very likely that a viewer will see the "shadow" of the light because the light beams are emitted directly toward the diffusion board 230. In order to effectively eliminate this unwanted, defective shadow, the diffusion board 230 made in accordance with the present invention provides a unique structure to soften the "shadow," thereby providing a shadow-free image by completely diffusing light beams projected into portions of the diffusion board 230 directly adjacent to the light sources 220.

**[0018]** The diffusion board 230 generally comprises a substrate 234 which is made of highly transparent material. The diffusion board 230 further includes a diffusion layer 235 formed directly upon the substrate 234. The diffusion layer 235 is made from a material such as Polymethyl Methacrylate (know as PMMA) or Polycarbonate (know as PC). The PMMA or PC is further blended with scattering material so as to increase the refractive efficiency thereof. The scattering material is selected from melamine resin or PMMA having a grain size of 5 to 30 micrometers.

**[0019]** Specially, when the diffusion layer 235 is formed, the diffusion layer 235 is configured to have first areas 236 and second areas 237. For the most part, the second areas 237 are positioned closer to the light sources 220, while the first areas 236 are positioned further away from the light sources 220. In order to eliminate the shadow generated by the light sources 220, the refractive index of the second areas 237 is

substantially larger than that of the first areas 236. By this arrangement, the light projected through the second areas 237 is scattered such that the shadow effect is diminished or eliminated.

[0020] The diffusion board 230 in accordance with a preferred embodiment of the invention is made using an injection process. The first areas 236 and the second areas 237 of the diffusion board 230 are injected with different materials. For example, the first areas 236 can be injected with normal transparent material, while the second areas 237 can be normal transparent material mixed with the scattering material, i.e., melamine resin or PMMA having a grain size of 5 to 30 micrometers. The two materials can be precisely positioned within a mold cavity. As a result, the second areas 237, being composed with a high density of scattering material, exhibit a higher refractive index. By this arrangement, the light beams projected from the light sources 220 into portions of the diffusion board 230 closer to the light sources 220 (i.e. the second areas 237) are effectively diffused within the diffusion board 230, thereby eliminating the light "shadow."

[0021] It can be easily appreciated that by providing the diffusion board 230 with areas having different refractive indices, the light "shadow" can be effectively eliminated without the use of a light curtain, such as that described in US Pat. No. 5,438,484 issued to Kanda.

[0022] In use, the light beams projected from the light sources 220 and reflected from the reflective film 211 penetrate into the diffusion board 230, which diffuses the light beams evenly. The refractive indices of the first areas 236 and the second areas 237 are specially tailored so that the light beams emitted from the emitting surface 232 are evenly distributed. As mentioned above, the second areas 237 are right above the light sources 220, and have a larger refractive index. Therefore the light beams penetrating through the second areas 237 are largely scattered by the scattering material. After the light beams are evenly emitted from the emitting surface 232, the light beams enter the enhancer 240, which intensifies their luminance.

[0023] In addition, the second areas 237 of the diffusion board 230 can be arranged to conform to the shape of the light sources 220. As shown in Figure 3, another light source 320 arranged within a refractor

frame 310 has a W-shaped configuration. The refractor frame 310 is further coated with a reflective film 311 so as to intensify the luminance. The W-shape light source 320 includes a pair of electrodes 321 for connection to a power supply. For this type of light source, the second areas 237 of the diffusion board 230 can be made with an arrangement corresponding to the shape of the light source 320. As a result, the "shadow" effect is again eliminated by the provision of scattering material within the diffusion board 230.

**[0024]** The embodiments described above are related to a penetrative type light source, i.e., the light source is arranged under the diffusion board. In cases of side-edge arranged light sources, the basic arrangement provided by the present invention can also be applied.

**[0025]** As shown in Figures 11 to 17 of the Kanda '484 patent, the light guide is divided into several sections, i.e., a single light guide comprises several different plates. However, when the basic arrangement in accordance with the present invention is introduced, the physical sections separated by surfaces are replaced by injected areas having higher and lower refractive indices due to higher and lower densities of scattering materials. By this arrangement, an integral light guide plate having different sections bearing higher and lower densities of scattering materials can easily achieve the effect sought by the Kanda device, while being easier to assemble, handle, and so on compared to the Kanda device.

**[0026]** It is to be understood, however, that even though numerous characteristics and advantages of the present invention have been set forth in the foregoing description, together with details of the structure and function of the invention, the disclosure is illustrative only, and changes may be made in detail, especially in matters of shape, size and arrangement of parts within the principles of the invention to the full extent indicated by the broad general meaning of the terms in which the appended claims are expressed.
